Excerpt from Remarks Concerning the Determination of Electron Distribution in the Ionosphere by Means of Radio Soundings For a number of years the pulse sounding method of Breit and Tuvs[i] has been one of the most important tools for investigating the structure of the ionosphere. In this method a pulse modulated electromagnetic wave with an appropriate carrier frequency is transmitted vertically from the ground toward the upper atmosphere, and the time delay of the reflected pulse as a function of the carrier frequency is measured. The analysis of data obtained by the method of Breit and Tuve has provided much of the conceptual picture of the ionosphere which investigators have formed. However, from time to time some doubt has been expressed in the literature about the validity of certain assumptions used to relate pulse sounding data to the ionosphere s structure. In fact, it appears likely that in many cases the mathematical analysis ordinarily applied is too crude even to justify certain conclusions which are almost qualitative in nature such as the number of distinct layers present or the heights of maximum electron densities during a given experiment. Some indication of the pitfalls which may occur in the usual analysis, as well as the possibility of improving the results will be discussed here.
