THE CONTROL OF THE TEMPERATURE IN WINE FERMENTATION (CLASSIC REPRINT) (PAPERBACK)

Forgotten Books, 2017. Paperback. Condition: New. Language: English . Brand New Book ***** Print on Demand *****. Excerpt from The Control of the Temperature in Wine Fermentation Excess of Heat. The amount of heat generated within the fermenting tank is very great, being sufficient, theoretically, to raise above boiling point the whole of a must rich in sugar. Practically, however, the heat is generated gradually; and much of it is carried off by the gas generated, as well as through the walls of the vat, and from the surface of the fermenting liquid otherwise fermentation beyond a certain point would be impossible. This fact has taught wine-makers in warm countries the necessity of a free circulation of air in the fermenting-room, unless that air is hotter than the temperature of the fermenting mass. Hence the benefit of the practice of fermenting in small packages with thin walls: first, because of less actual amount or quantity of heat (calories) generated and, second, because of the facility with which this heat can be carried off and thus the equilibrium between the temperature of the fermenting mass and the outside air be maintained. This has led many wine makers to have their tanks made of small diameter, of great height, and of very thin material of high conductivity, such as thin enameled iron. While this certainly enables the operator to completely control the temperature, it has proved far too expensive for general use. But unquestionably the growing custom of using very large tanks is essentially bad practice. Activity of t/ze Yeast. The third factor in the problem is the activity of the yeast-cell. There are many circumstances that modify this activity. First it must be remembered that the yeasts are plants, and that, in a general way, their growth...
