Of the many electrical check-tests made with this type of apparatus, but one need be given here, pending a special treatment of the method of control of the calorimeter in a forthcoming publication. An electrical checkexperiment with the chair calorimeter was made on January 4, 1909, and continued 6 hours. The voltmeter and mil-ammeter were read every few minutes, the water collected in the water-meter, carefully weighed, and the temperature differences as measured on the two mercury thermometers were recorded every 4 minutes. The heat developed during the experiment may be calculated from the data as follows: Average current= 1.293 amperes; average E. M. F. = 109.15 volts; time = 21,600 seconds; factor used to convert watt-seconds to calories=0.2385. $(1.293 \times 109.15 \times 21600 \times 0.2385) \times 1.001 = 727.8$ calories produced. During the 6 hours 237.63 kilograms of water passed through the absorbing system. The average temperature rise was 3.04 C, the total heat brought away was therefore $(237.63 \times 3.04) \times 1.0024 = 724.1$ calories. Thus in 6 hours there were about 3.7 calories more heat developed inside the apparatus than were measured by the water-current, a discrepancy of about 0.5 per cent. W. O. Atwater and E. B.
